## Distance Decay (Betas) ${ }^{1}$

In the absence of survey data, trade flows between regions are often estimated by a gravity equation. One form of such an equation specifies that for a given industry, trade flows between two regions is determined by the interaction of the industry's output in the region of origin and of demand in the region of destination. The intensity of interaction is measured by the distance between the two regions and a distance decay parameter beta. Thus, for any given industry,

$$
\begin{equation*}
T_{i j}=A_{i} B_{j} Q_{i} D_{j} / d_{i j} \text { beta } \tag{1}
\end{equation*}
$$

where $\quad \mathrm{T}_{\mathrm{ij}}$ is the trade flow between the region of origin i and the region of destination $j$
$Q_{i} \quad$ is the output in the region of origin $i$
$D_{j} \quad$ is the demand in the region of destination $j$
$\mathrm{d}_{\mathrm{ij}} \quad$ is the distance between region i and region j estimated from longitude and latitude data
beta is the distance decay parameter to be estimated
$A_{i}, B_{j}$ are balancing factors to be estimated

$$
\begin{align*}
A_{i} & =\left(\sum \mathrm{B}_{\mathrm{j}} \mathrm{D}_{\mathrm{j}} \mathrm{~d}_{\mathrm{ij}}^{\text {-beta }}\right)^{-1}  \tag{2}\\
\mathrm{~B}_{\mathrm{j}} & =\left(\sum \mathrm{A}_{\mathrm{i}} \mathrm{Q}_{\mathrm{i}} \mathrm{~d}_{\mathrm{ij}}^{- \text {beta }}\right)^{-1} \tag{3}
\end{align*}
$$

The $A_{i}$ and $B_{j}$ ensure the following constraints are satisfied,

$$
\begin{aligned}
& Q_{i}=\Sigma T_{i j=1} \\
& D_{j}=\Sigma T_{i j}{ }_{i=1}
\end{aligned}
$$

[^0]
## Data \& Methodology

The parameter beta and factors $A$ and $B$ are estimated simultaneously using an iterative procedure where a value of beta is found at the point where the value of the objective function is a minimum. A and $B$ are evaluated at that optimum beta using equations (2) and (3) above.

The objective function is evaluated as the sum of squares of differences between actual changes in output in the region of origin and the estimated changes of that output. The estimated change of output is determined by the change in demand in the demanding regions modified by the distance and the distance decay parameter beta.

This iterative procedure does not require the use of actual trade flows to estimate beta and $A$ and $B$.

The data set used is a panel data set of output Q and demand D for 3086 counties and years 1990 thru 2007. The Qs and Ds are normalized to the U.S. Qs and Ds. The Qs are adjusted for exports to get domestic output, and the Ds are adjusted for imports to get local demand that is satisfied by local supply.

With a starting value of beta, the optimizing routine is iterated until the beta converges to a value within its lower and upper bounds at the point that the value of the objective function is a minimum.

## Results

Several approaches were used in order to generate a set of estimates that were both reasonable and relatively consistent with the previous estimates, which were based on a different time series (1969-1996 instead of 1990-2007), a different level of geographic detail (state data instead of county data), and a different industry definition (Standard Industrial Classification instead of NAICS). Estimates utilizing log in the distance function were made based on county to county as well as state to state data, in addition to those utilizing county data and a power of 0.3 as well as a power of 0.4. From these four sets of estimates, the following set of betas were selected.

|  |  | New <br> Beta <br> Estimate | Previous <br> Beta <br> Estimate |

## Price Elasticity of Demand (Sigmas) ${ }^{2}$

The price elasticity of demand is derived from interregional trade flows. For a given industry, it is hypothesized that the change in output in the supplying region is determined by two factors, (1) the change in demand that results from a shift of the demand curve in the demanding regions, and (2) the change in demand that results from the movement along the demand curve or by a change in price in the supplying region.

Thus,

$$
\begin{equation*}
\Delta Q / Q=\Delta E D S / E D S+\Delta E D M / E D M \tag{1}
\end{equation*}
$$

or $\quad \Delta \mathrm{Q} / \mathrm{Q}-\Delta \mathrm{EDS} / \mathrm{EDS}=\Delta \mathrm{EDM} / \mathrm{EDM}$
where,
$\Delta \mathrm{Q} / \mathrm{Q} \quad$ is the rate of change of output in supplying region
$\Delta E D S$ / EDS is the rate of change in demand resulting from a shift of the demand curve in the demanding regions
$=\left(\sum S_{i j}\left(\Delta D_{j}\right)\right) /\left(\left(\sum S_{i j} / D_{j}\right)\right.$
 price or from the movement along the demand curve.

$$
\begin{equation*}
=\quad(1-\sigma)\left[\left(\Delta \Omega_{\mathrm{i}} / \Omega_{\mathrm{i}}\right)-\left(1 / \mathrm{Q}_{\mathrm{i}}\right)\left(\Sigma \mathrm{S}_{\mathrm{ij}} \mathrm{D}_{\mathrm{j}}\left(\Sigma \mathrm{~S}_{\mathrm{ij}}\left(\Delta \Omega_{\mathrm{i}} / \Omega_{\mathrm{i}}\right)\right)\right]\right. \tag{4}
\end{equation*}
$$

and for each industry,
$S_{i j}=A_{i} B_{j} Q_{i} d_{i j}^{-\beta} \quad$ is the share of domestic demand in region $j$ supplied by region I
$\sigma \quad$ is the demand price elasticity

[^1]$\Omega_{\mathrm{i}} \quad$ is the cost of production in region of origin
$\Delta \Omega_{\mathrm{i}}$ is the change in the cost of production in region of origin
$D_{j} \quad$ is the total demand in region of destination $j$
$\mathrm{d}_{\mathrm{ij}} \quad$ is the distance between regions i and j
$\beta \quad$ is the distance decay parameter from the gravity model
$A_{i}, B_{i}$ are balancing factors from the gravity model
$Q_{i} \quad$ is the total output in supplying region

## Regression

Substituting equations (3) and (4) into equation (2) produces the regression equation with $1-\sigma$ as the coefficient of the right-hand side. The data used is a panel data set of output, Q, and demand, D, generated by the REMI modelbuilding system for 3086 counties and for years 1990 thru 2007. The county data is normalized to the U.S. data. The output is adjusted for exports to get domestic output and the demand is adjusted for imports to get local demand satisfied by local supply. A time fixed effects regression model is used to estimate the coefficient 1-б.

## Results

The sigmas estimated here are consistent with the betas shown above, as well as with the As and Bs , as can be seen in equation (5) above.

[^0]:    ${ }^{1}$ The following discussion is based on an unpublished paper Inter- and Intra-State Trade Flow Estimation in the Absence of Trade Flow Data by George Treyz, Omar F. El-Gayar and Frederick Treyz as well as its implementation in a Fortran computer program.

[^1]:    2 The following discussion is based on notes from Omar El-Gayar's binder of computer runs and on the Fortran computer program that implemented the formulas from these notes.
